X-Ray Attenuation

- At CT energies, linear attenuation μ is the result of 2 microscopic interactions between X-ray photons and tissue:
 - Photoelectric absorption (effect): μ_p
 - Compton scattering: μ_c

Photoelectric absorption

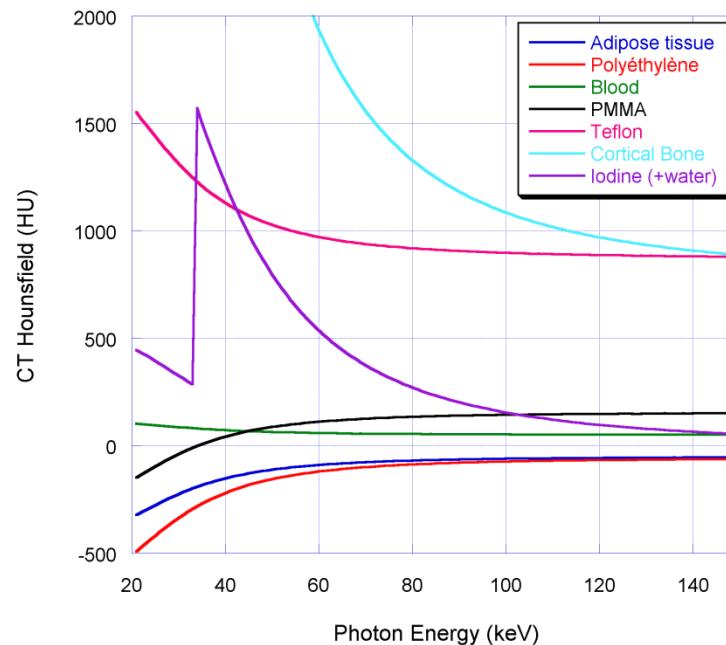

Compton scattering

$$\mu = \mu_p + \mu_c$$

X-Ray Attenuation

- X-ray attenuation depends on the incident X-ray energy and on the effective atomic number of the traversed tissue
- Different tissues exhibit different combinations of photoelectric absorption and Compton scattering

$$\mu(E) = \mu_p(E) + \mu_c(E) = \alpha_p f_p(E) + \alpha_c f_c(E)$$

X-Ray Attenuation

- X-ray attenuation depends on the incident X-ray energy and on the effective atomic number of the traversed tissue
- Different tissues exhibit different combinations of photoelectric absorption and Compton scattering

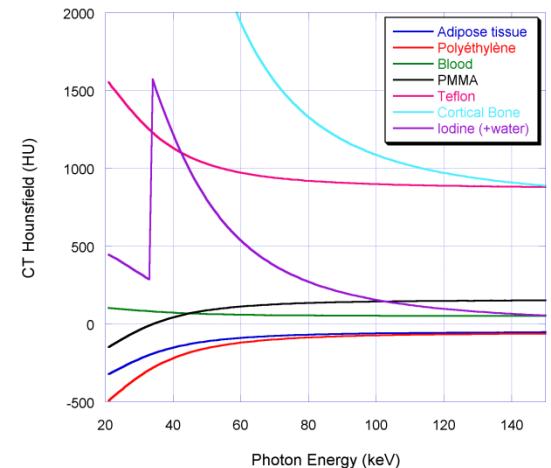

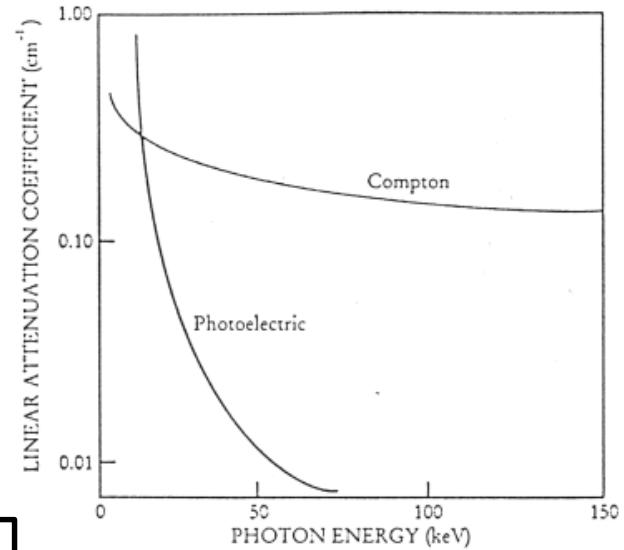

$$\mu(E) = \mu_p(E) + \mu_c(E) = \alpha_p f_p(E) + \alpha_c f_c(E)$$

(α_p, α_c) : characteristic of material/tissue

$$\begin{cases} \alpha_p \propto \rho Z_{eff}^{3.8} \\ \alpha_c \propto \rho Z_{eff} \ , \rho \text{ is the mass density} \end{cases}$$

(f_p, f_c) : independent of material, only dependent on energy *

$$\begin{cases} f_p(E) \propto 1/E^{3.2} \\ f_c(E) \text{ is the Klein-Nishina function: weakly dependent on energy } E \end{cases}$$

* Alvarez R.E. and Macovski A., Energy-Selective Reconstructions in X-ray Computerized Tomography, Phys.Med.Biol. 1976, 21(5), 733-744.

X-Ray Attenuation

- X-ray attenuation depends on the incident X-ray energy and on the effective atomic number of the traversed tissue

- The **atomic number Z** is the number of protons found in the nucleus of an atom. Example: Hydrogen Z=1, Oxygen Z=8

- The **effective atomic number Z_{eff}** is a term similar to the atomic number Z but is used for compounds

$$Z_{eff} = \sqrt{f_1(Z_1)^{2.94} + f_2(Z_2)^{2.94} + f_3(Z_3)^{2.94} + \dots}$$

Where f_n is the fraction of the total number of electrons associated with each elements and Z_n is the atomic number of each element

e.g. water H₂O $\rightarrow Z_{eff} = \sqrt{0.2(1)^{2.94} + 0.8(8)^{2.94}} = 7.42$

	Z_{eff}
Gadolinium	64.0
Iodine	53.0
Calcium	20.0
Cortical Bone	13.23
Water	7.42
PMMA	6.52
Fat	5.92

Dual-Energy Acquisition

$$\begin{cases} \mu(E_L) = \alpha_P f_P(E_L) + \alpha_c f_c(E_L) \\ \mu(E_H) = \alpha_P f_P(E_H) + \alpha_c f_c(E_H) \end{cases}$$

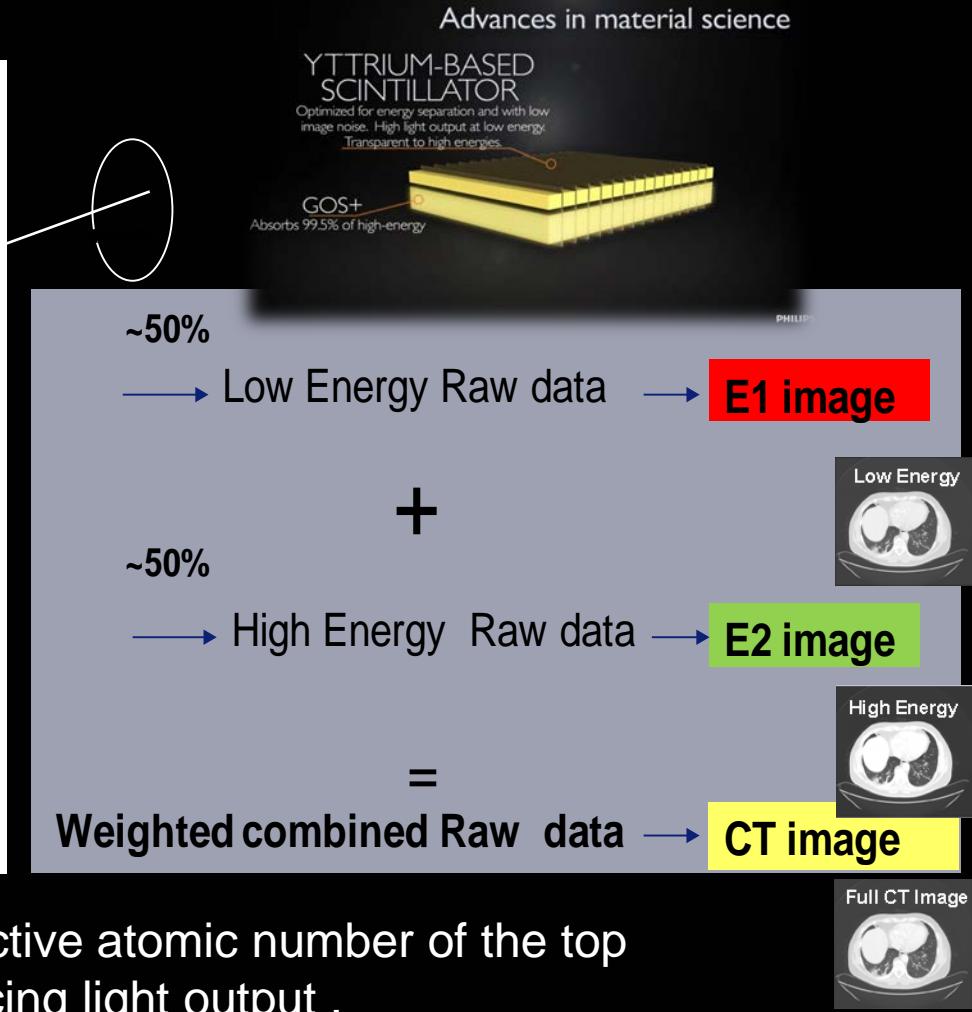

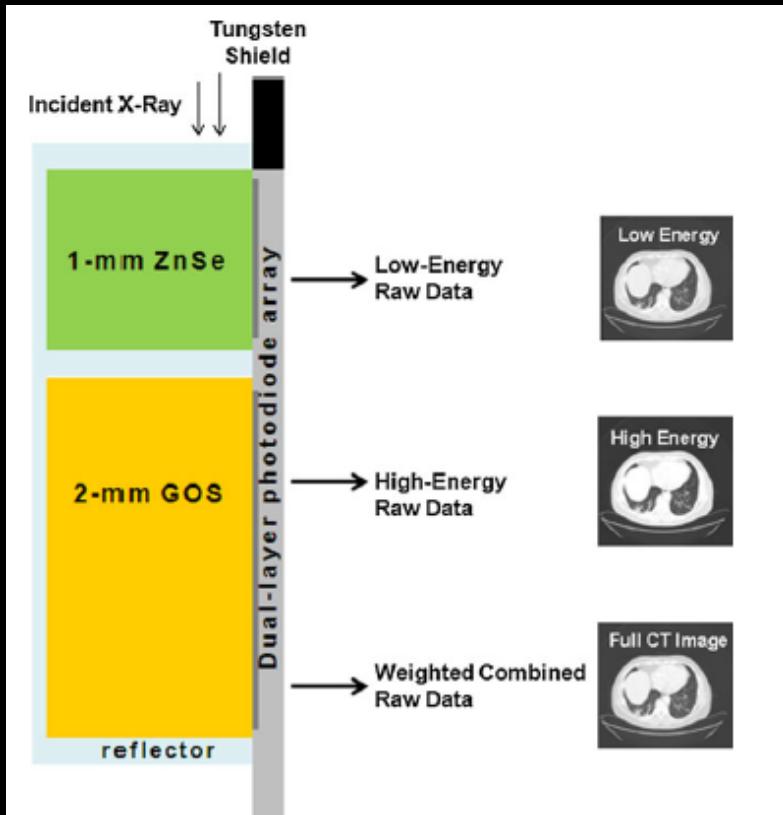

Solve for α_p and α_c

Different materials/tissues are characterized by their unique pair of attenuation parameters (α_p , α_c)

Different materials/tissues that may lay out same HU values in single acquisition CT can now be “characterized” using the dual-energy CT by measuring (α_p , α_c)

Polychromatic nature of the beam can be corrected in the calculation of α_p and α_c if the x-ray spectrum **is known** *

The dual layer Spectral Detector, Principle and Operation

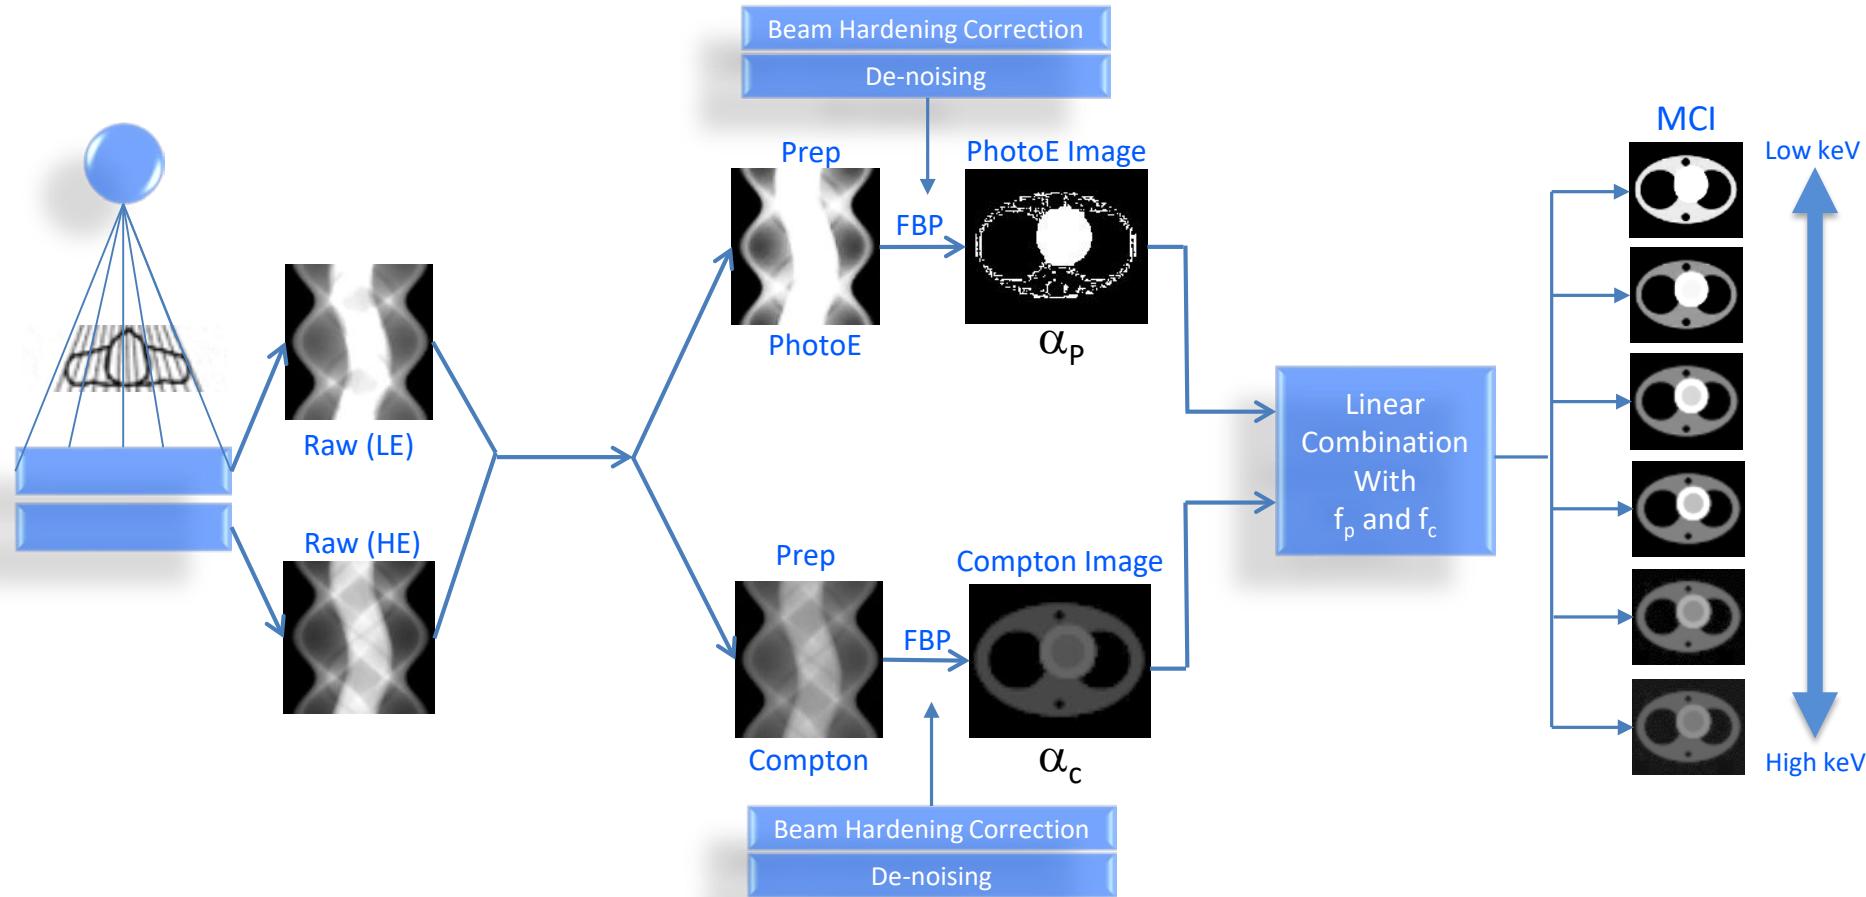

1. For optimal performance the effective atomic number of the top scintillator is small without sacrificing light output .
2. Top Scintillator thickness has been optimized for best energy separation and low-energy image noise
3. Bottom scintillator is GOS, the thickness of which set to absorb 99.5% of the High-Energy spectrum (note that light collection is sideways)

Photoelectric - Compton Decomposition

Material Decomposition

Material Decomposition Overlay images)

Spectral Imaging improves clinical diagnostic

Body Area	Type of pathology	Spectral Benefit
Cardiac & CTA	Plaque	Plaque characterization using EffZ, MonoE
	Perfusion deficit	Increased conspicuity & reduced BH artifact
	Calcium in vessels	Reduced Calcium Blooming
	Large patient & with TRO	No limitation of FOV & full dose modulation tools available
	Missed injection (or reduced iodine dose)	Boost of iodine signal at lower keVs
CT Angiography (Head, Body, Extremities)	Plaque	Plaque characterization using EffZ, MonoE
	Calcium	Reduced Calcium Blooming
	Missed injection (or reduced iodine dose)	Boost of iodine signal at lower keVs
	Compare NC & VNC	Generation of VNC to eliminate NC series
	Vessel assessment	Better bone removal

Spectral Imaging improves quality of clinical diagnostic

Body Area	Type of pathology	Spectral Benefit
Oncology	Lesion	Increased sensitivity to detection of iodine uptake
	Focal lesions	Increased sensitivity to detection of iodine uptake
	Incidental findings	VNC where NC was not done
	Treatment follow up	Differentiation of hemorrhage vs iodine
	Lung nodule	Differentiation of tumor vs vessels using iodine maps & VNC
	Brain tumor	Differentiation of iodine vs hemorrhage within tumor
	Thyroid nodules	Benign vs malignant
Head	Posterior fossa assessment	Beam hardening reduction in PF region
Metal implants	Metal implants	Artifact reduction
Metabolic	Kidney stones	Detection & characterization
	Gout	Detection & characterization

Abstract

Objectives: To evaluate the image quality and lesion conspicuity of arterial-monoenergetic imaging (VM) and dual-layer DECT without increasing iodine dose compared with standard 120-kVp protocol.

Key words: Dual-layer DECT, multiphasic hepatic CT, dual-energy hepatic CT, dual-energy CT, DE-DECT

Methods: Fourteen subjects with abdominal diseases who had undergone hepatic CT using 300-mg I/ml were included. VM (120 kVp DE-DECT VMI) was performed at each phase using a 120-kVp tube voltage. A matched-pair matched scanning mode (40–55 keV) was used for DECT. DECT protocol doses were reduced by 40–60% compared with 120-kVp scans with iterative reconstruction.

Results: Image quality and lesion conspicuity of hepatic hilar carcinomas were similar to those of 120-kVp scans.

Arterial VMDE was significantly lower in the DE-DECT group ($p < 0.05$) than image quality of DE-DECT VMI was almost comparable to that of 120-kVp DECT. Arterial VMDE and CNR also gradually increased. The values of 31–40 keV images were almost equivalent to those of intended 120-kVp. The highest scores for overall quality and lesion conspicuity were obtained at 40–55 keV. In all cases, 40–55 keV, all of which were comparable to or better than 120-kVp.

Conclusion: For multiphasic hepatic CT with 50% iodine load, DE-DECT VMI at 40–45 keV provides

equivalent or better image quality and lesion conspicuity without increasing iodine dose compared with standard 120-kVp protocol.

Key words: Dual-layer DECT, multiphasic hepatic CT, dual-energy hepatic CT, dual-energy CT, DE-DECT

Abstract

We evaluated the feasibility and extent to which iodine concentration can be reduced in computed tomography angiography (CTA) of the aorta and coronary arteries using low tube voltage and virtual monoenergetic imaging of 1-layer dual-energy CT (DECT) results. A circulation phantom was imaged with dual-source CT (DSCT), position-spectral imaging (PSI) and dual-layer spectral detector CT (SPECT). For each scanner, a reference scan was acquired at 120 kVp using routine iodine concentration. Subsequent scans were performed at 100 kVp and 80 kVp using 40–60% iodine reduction. DECT images were acquired at 120 kVp, 80 kVp and 60 kVp, respectively. In arterial phase after administration of iodine (300, 240, 180, 120, 60, 30 mg I/ml), objective image-quality was evaluated using DSCNR and dose normalized CNR (DCNCR) in the aorta and left main coronary artery. Average DCNCR at reference was 227.8, 39.3 and 60.2 for DSCT, PSI and SPECT, respectively. At 100 kVp, DCNCR was 214.1, 34.6 and 53.1, respectively. At 80 kVp, DCNCR was 140.5 (reduced for DECT) (DCNCR 46.1) and 63.6 (DCNCR 44.1) using conventional CT low kVp and 20 kVp (iodine 69% reduced for DECT) (DCNCR 17.1) using DECT mode. Low kVp scanning and DECT allows for 40–60% iodine reduction without loss in image quality compared to reference. Optimal scan protocol and iodine extent varies per vendor. Further studies are needed to extend and translate our findings in clinical practice.

Objectives: To estimate the potential dose reduction in individual patients when interpreting monoenergetic images synthesized from dual-layer detector spectral CT (DSCT).

Methods: Sixty-four patients received contrast-enhanced CT scans of the abdomen with iodine concentrations ranging from 100 to 300 mg I/ml. Objective image-quality was evaluated using arterial, 120 kVp and 80 kVp images. The iodine concentration in the arterial vessels was measured relative to surrounding tissue. CNR (image-to-noise ratio) was calculated for DSCT (DCNCR 46.1) and GSI (DCNCR 44.1) using conventional CT low kVp and 20 kVp (iodine 69% reduced for DSCT) (DCNCR 17.1) using DECT mode. Low kVp scanning and DECT allows for 40–60% iodine reduction without loss in image quality compared to reference. Optimal scan protocol and iodine extent varies per vendor. Further studies are needed to extend and translate our findings in clinical practice.

Abdomen: Use of a novel, single-source, dual-layer detector spectral CT scanner to improve vascular image quality and reduce contrast dose while maintaining the amount of iodine required for reduction in oncology treatment planning.

Keywords: Iodinated contrast media · Dual-energy CT · Thoracic aorta · Low kVp · Image quality

Introduction: Contrast-enhanced CT scans are frequently performed in radiation oncology departments for treatment planning to better identify blood vessels for the purpose of radiotherapy. Radiation therapy is a form of cancer treatment that uses high-energy x-rays to shrink tumors. X-rays pass through the body and are absorbed by dense structures such as bone and fat. Tissues with less dense structures, such as muscle and organs, absorb fewer x-rays. This difference in absorption creates a contrast between normal tissue and cancerous tissue, allowing the physician to identify cancerous tissue and plan treatment accordingly.

Contrast-enhanced CT scans are frequently performed in oncology departments for treatment planning to better identify blood vessels for the purpose of radiotherapy. Radiation therapy is a form of cancer treatment that uses high-energy x-rays to shrink tumors. X-rays pass through the body and are absorbed by dense structures such as bone and fat. Mono Chromatic Imaging in Iodine volume reduction

70sec delay

120keV

45keV

Iodine volume reduction

An elderly patient with a history of aortic valve stenosis and renal insufficiency was referred for a pre-TAVI CTA, but was unable to tolerate the full volume of contrast necessary to obtain needed information from conventional CT.

CTDlvol: 14.6mGy

DLP: 657mGy × cm

*Effective Dose: 9.8mSv
(k=0.015)**

Courtesy of University Hospital, Cleveland

Improvement of imaging in contrast studies /iodine boosting phenomena/

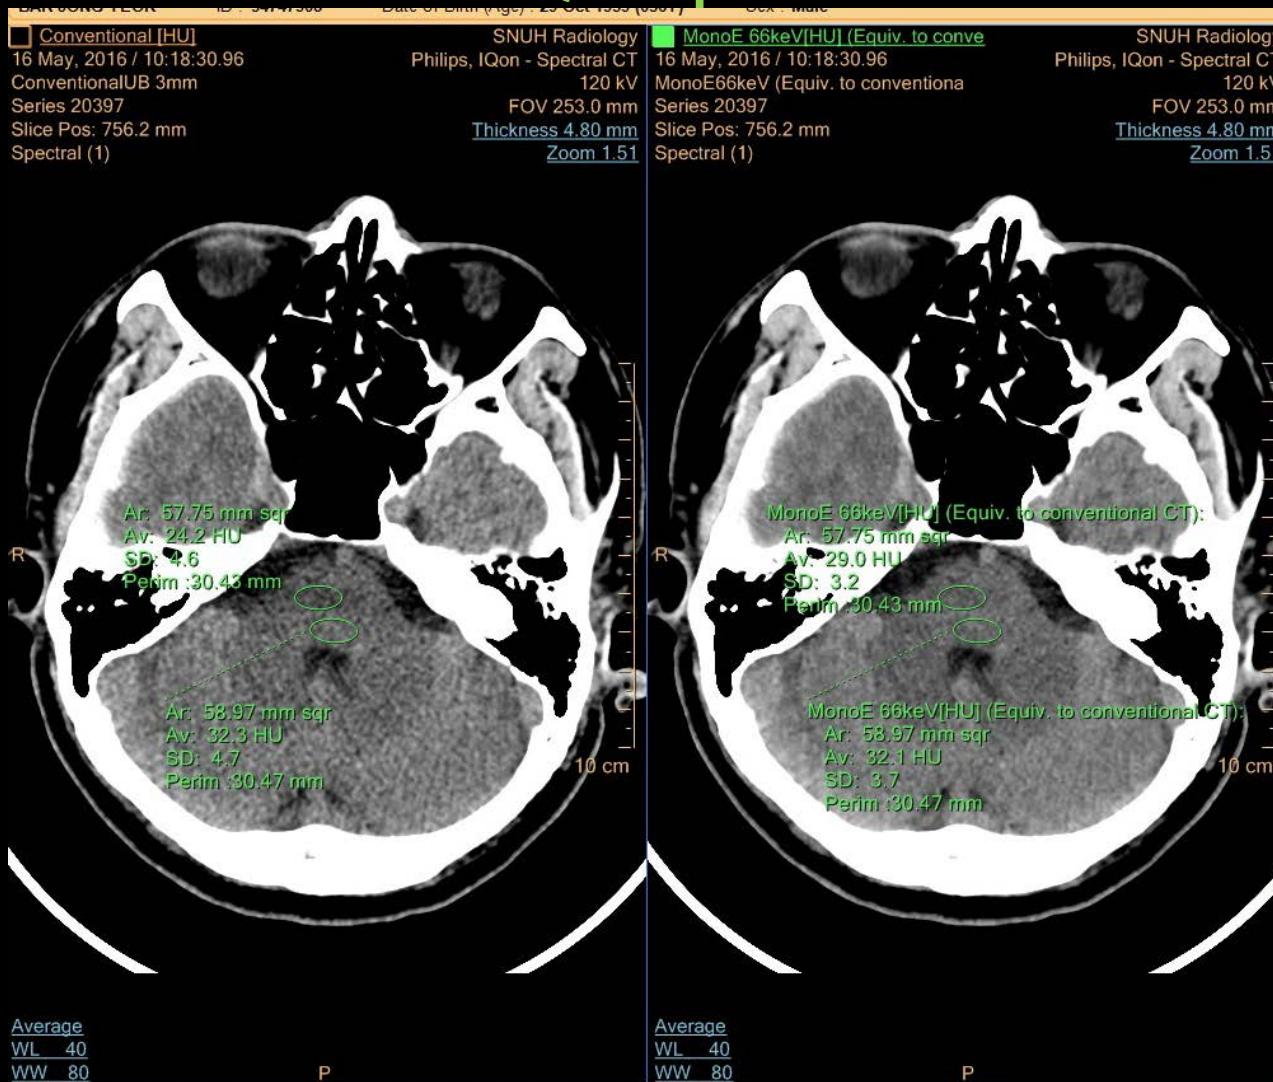

- Contrast improvement in imaging
- Visualization of enhancement even by small amount of contrast
- Missed contrast injection
- Ruptured veins
- Renal dysfunctions in oncological patients

CM dose reduction!

New spectral CT IQON

HLAVA

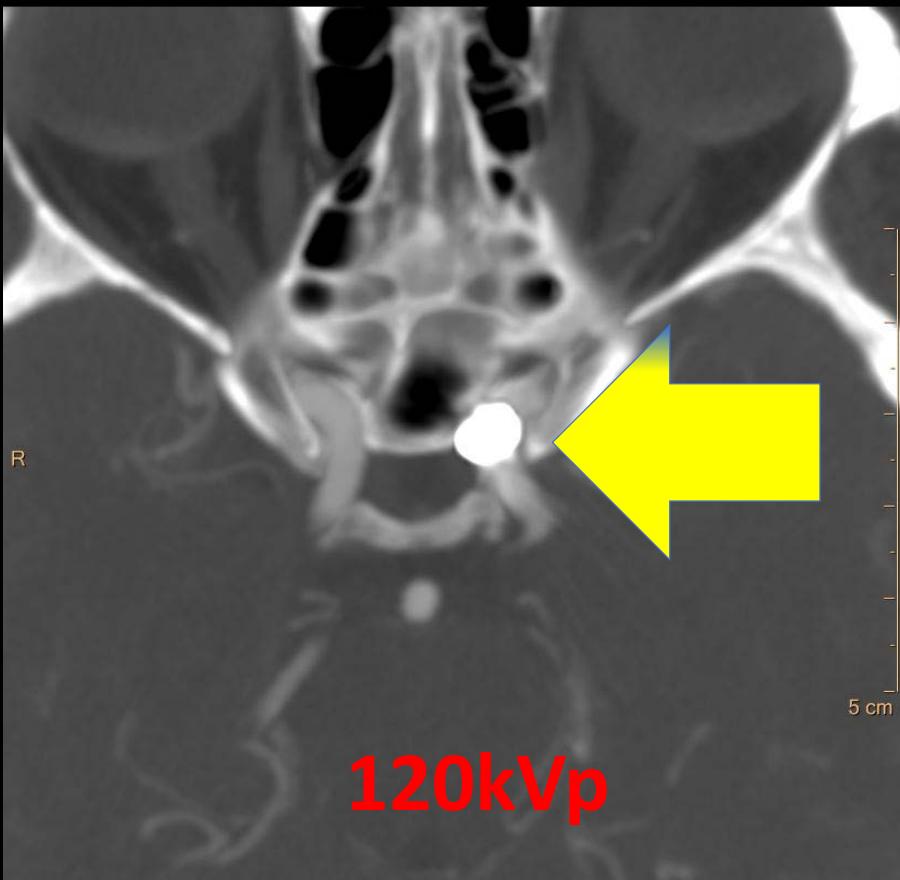

Brain IQ improvement

8 HU difference in the PF area of similar attenuations areas in conventional were reduced to 3 HU difference in the equivalent monoE (66).

By extraction of metallic implantation – superior visualization of ICA left

Přehled bodů

- Spektrální CT – cesta k innovaci + trochu teorie
- Klinicko- technické benefity spektrálního CT
- Klinické příklady aplikací spektrálního CT dle anatomie
- Jaké jsou možnosti dalších inovací

- Postprocessing /ISP
- AI v CT oblasti

Acting as New research tools

- Perfect separation due to anti-correlated noise
- Perfect calculation of beam hardening – thus better material decomposition
- New possible approaches like **iron, AEF, ECV, fibrosis, 3TP perfusion, radiotherapy maps**

Take home messages

- Spektrální CT není stejné jako CT s dvojí energií
- Řešení cestou spektrálního dvojitěho detektoru je technický předstupeň pro nové photocountingové CT systémy
- Spektrální informace je v každém skenu bez nutnosti selekce operátora
Díky isotemporální spektrální informaci není nutno snímky registrovat
- Nejmenší isotropický spektrální voxel = zlepšení diagnostiky a
diagnostické jistoty /DCE/
- Není kompromis u bariatrických pacientů, neklidných pacientů apod.
- Řešení cestou spektrálního dvojitěho detektoru je nezávislé pak na
technických možnostech vlastního přístroje /0,27s RT, multicycle recon
apod./

Děkuji vám za milou pozornost!

Děkuji též kolegům z firmy Philips
